

SINGLE-STAGE LIQUID RING VACUUM PUMP

To produce vacuum in a single-stage liquid ring vacuum pump, a multiblade impeller on a shaft is positioned eccentrically in a cylindrical housing that is partially filled with sealing liquid.

Flat Plat Design

Conical Design

As the shaft turns, a liquid ring is created by the centrifugal force generated by the rotating impeller. This force holds the liquid ring against the inner wall of the pumping chamber. Since the impeller is located eccentric to the pumping chamber, the depth of entry of the blades into the liquid ring decreases and increases as the impeller rotates. This creates increasing cell volume on the inlet port side, creating vacuum.

Flat Plat Design

Conical Design

On the discharge port side, the impeller cell volume decreases as the blades move further into the liquid ring. This increases the pressure until discharge takes place through the discharge port.

A continuous flow of fresh sealing liquid is supplied to the pump via the sealing-liquid inlet.
